

HYBRID APPROACH FOR ORDER-BASED OPTIMIZATION
USING EVOLUTIONARY ALGORITHMS: CASE OF CAPACITATED
VEHICLE ROUTING PROBLEM

Rihab Gorsane, Sana Mrabet, Khalil Gorsan Mestiri

ABSTRACT

Evolutionary Algorithms (EA) have proved their efficiency in solving combinatorial optimization problems. However, in the literature, the proposed solutions focused on the use of a single crossover and/or mutation operators. Hence, our work studies the possibilities of classifying and combining these variation operators resulting in a better performance. We propose a Hybrid Genetic Algorithm combining different strategies and operators in pursuance of a better population diversity and elitism preservation. The HGA is applied to the Capacitated Vehicle Routing Problem (CVRP) and it could be easily extended to any problem that could be formulated as an order-based optimization problem.

PROBLEM FORMULATION

The vehicle routing problem (VRP) is an important problem class in the field of operations research and transport logistics optimization. Its original formulation has been defined over 60 years ago by [1] and consists of a fleet of identical vehicles serving a set of customers with a certain demand from a single depot and having a certain capacity. This formulation is referred to as the capacitated vehicle routing problem (CVRP). The CVRP can be stated as follows:

min \sum_{i=0}^N \sum_{j=0}^N \sum_{k=1}^K d_{ij} X_{i,j}^k

where X_{i,j}^k = \begin{cases} 1 & \text{if the vehicle } V_k \text{ travels from node } i \text{ to node } j \\ 0 & \text{otherwise} \end{cases}

Determining the optimal solution to CVRP is NP-Hard since it has to verify a set of constraints:

- Each customer has to be visited only once.
- The total demand of the customers being served by a vehicle does not exceed the vehicle capacity.
- All routes start and finish at the depot.
- There are a maximum of K routes for serving the customers.

Solution Encoding as Order-Based Representation

To encode CVRP solution, we used a vector representation encapsulating the significant informations for each individual.

ALGORITHM: THE HYBRID STEADY STATE GENETIC ALGORITHM (HSSGA)

- 1: Initialize population with N feasible solutions
- 2: Evaluate initial population
- 3: **While** Non Stop Condition **do**:
- 4: Select two parents(Pi ,Pj) from the population using tournament selection
- 5: C ← Reproduction(Pi ,Pj) // Random or Balanced Hybridization
- 6: Select randomly an individual W from the population's second half according to either fitness or violation rate
- 7: Replace W with C in the population
- 8: **end**

HYBRIDIZATION STRATEGIES

One of the main problems encountered when using the same operators class for both crossover and mutation is Premature Convergence. It occured when the population converges too early, exposing that the genetic operators are not able to generate offsprings outperforming their parents. To prevent this phenomenon, combining these operators regarding their nature (exploitative or explorative) can lead to better performance. We designed the two hybridization strategies below :

- Random Hybridization: It consists of selecting randomly a crossover and mutation operators and use them respectively to generate an offspring.
- Balanced Hybridization: It aims to balance the GA exploration and exploitation abilities by mixing heuristic operators with position operators.

STEADY STATE

The steady state genetic algorithm is a simpler version of the generational and consists of selecting two parents, crossing and mutating them, to finally obtain an offspring inserted to the population. Compared to generational replacement, where a larger portion of the population is replaced, It was shown in [2] that genetic drift is accelerated when using steady state replacement instead of generational replacement.

COMPUTATIONAL RESULTS

We compared our results to the current best results available online (accessed on August 5th 2019). We record the best found solution as well as the worst in each of 30 independent, randomly initialized GA runs using different hybridization strategies.

The results are listed in Table.1

| Instance | C | Q | V | BKS | Random Hybridization | | | | Balancing Hybridization | | | |
|---------------|----|-----|----|------|----------------------|-------|---------|-------------|-------------------------|-------|---------|-------------|
| | | | | | Best | Worst | Average | % Deviation | Best | Worst | Average | % Deviation |

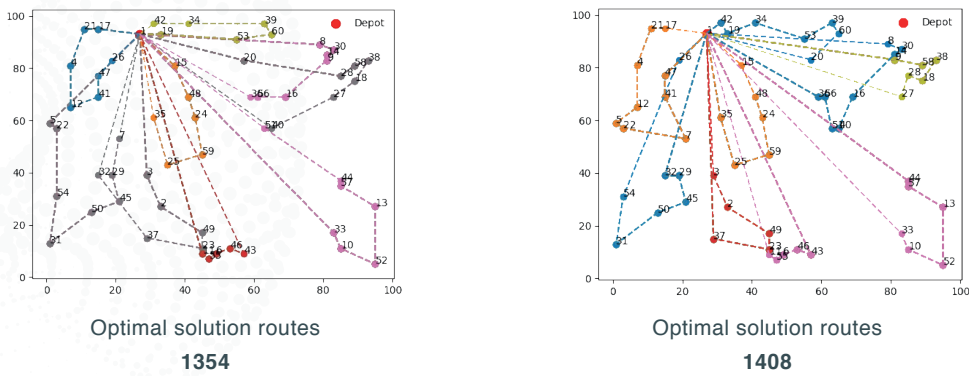

Figure.2 : Random vs Balanced hybridization

Conclusion

The conducted work expose that evolutionary algorithms can lead to remarkable results for solving the CVRP problem. Nevertheless, different strategies involving the nature of crossover/mutation operators, the selection methods, and replacement strategies affect the population evolution and fitness. Taking the described factors into consideration, two strategies were designed and were able to act optimally on some instances while delivering good solutions on others. Thus, It can be concluded that problem-specific tuning would be necessary for instances more than 60 customers.
